

AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

TNSkills Project | Professional Project Workflow & Documentation

Project	Auto Ticket Classification using Flow Designer	Platform	ServiceNow
Domain	IT Helpdesk / Incident Management	Automation	Flow Designer
Objective	Automatically classify incident tickets using keywords in Short Description and Description.	Repository	ServiceNow / Auto-Ticket

1. Project Overview

The school IT helpdesk receives multiple incident requests from students and teachers, including Wi-Fi issues, projector failures, password problems and slow-computer complaints. Manual review and classification of every request is time-consuming. This project uses ServiceNow Flow Designer to automate classification by analyzing keywords in the incident Short Description and Description fields.

2. Problem Statement

Manual ticket classification can increase handling time and may result in inconsistent categorization. A rule-based automation is required to identify common incident types and update the ticket consistently.

3. Project Objectives

- Capture newly created or updated incident tickets.
- Read the Short Description and Description fields.
- Analyze predefined issue-related keywords.
- Identify the applicable incident category.
- Automatically update the incident record.
- Send an email or notification when configured.
- Validate the solution through structured testing.

4. End-to-End Workflow

5. Project Milestones

Milestone	Phase	Key Activities	Deliverable
1	Requirement Analysis & Planning	Understand the helpdesk problem; identify incident fields; define categories, keywords and workflow.	Requirements and workflow plan
2	Backend Development & Configuration	Configure incident data, fields, categories and supporting application logic.	Configured ServiceNow setup
3	Automation using Flow Designer & Email Notification	Create trigger; analyze incident text; apply conditions; classify/update the ticket; configure notifications.	Working automation flow
4	Testing, Validation & Security	Test valid, invalid, unmatched, missing-data and access/security scenarios.	Validated test results
5	Deployment & Conclusion	Finalize configuration, documentation, demo evidence and project conclusion.	Deployment and final documentation

6. Detailed Implementation Workflow

Step 1 — Incident Trigger

The flow starts when a new incident is created or when the configured update condition is met.

Step 2 — Collect Incident Text

The flow reads the Short Description and Description fields from the incident record.

Step 3 — Keyword Analysis

The incident text is checked against predefined keywords for common issue types such as Wi-Fi, projector, password and computer performance.

Step 4 — Classification

When a condition matches, the corresponding incident category is selected. Specific conditions should be evaluated appropriately to avoid incorrect matches.

Step 5 — Update Incident

The selected classification is written back to the incident record for consistent routing and handling.

Step 6 — Email / Notification

The configured email or notification is sent to the relevant user or support team.

Step 7 — Testing & Validation

The completed flow is tested using representative scenarios, unmatched inputs and edge cases before deployment.

7. Example Classification Rules

Sample Keywords	Classification
Wi-Fi, wireless, network, internet	Network / Wi-Fi Issue
Projector, display, HDMI, screen	Projector / Display Issue
Password, login, sign-in, reset	Password / Access Issue
Slow, lag, performance, computer	Computer Performance Issue
No matching keyword	Manual Review / Default Handling

8. Testing & Validation

Test Case	Input Example	Expected Result
Wi-Fi issue	Wi-Fi not connecting in classroom	Network / Wi-Fi classification
Projector issue	Projector shows no display	Projector / Display classification
Password issue	Unable to reset password	Password / Access classification
Slow computer	Computer is very slow	Computer Performance classification
No keyword	Request does not match a defined rule	Default / manual handling
Missing description	Short Description only or blank Description	Flow handles input safely

9. Expected Benefits

- Reduces manual effort required for initial ticket classification.
- Improves consistency in incident categorization.
- Supports faster ticket routing and handling.
- Creates a repeatable and documented classification process.
- Provides a foundation for adding more categories and automation rules.

10. Project Deliverables

- Requirement analysis and workflow document
- ServiceNow configuration
- Flow Designer automation
- Email / notification configuration
- Testing and validation evidence

- Deployment and conclusion documentation
- GitHub project repository and demo evidence

11. Project Evidence

The GitHub screenshot has been updated to display ServiceNow instead of the previous repository owner name. The TNSkills project screenshot is included as supporting evidence.

12. Conclusion

The Auto Ticket Classification project converts a manual IT helpdesk classification activity into a structured ServiceNow Flow Designer automation. By analyzing incident text, applying predefined keyword rules, updating the ticket and sending notifications, the solution supports a faster and more consistent helpdesk process.
